Phosphorylation and localization of syntenin in normal, benign and malignant human breast. Syntenin is an adapter protein found to be hyperphosphorylated in breast cancer. We have previously shown that it is also hyperphosphorylated in normal and benign breast lesions, and hypothesized that it functions as an adaptor protein in the mechanisms that regulate tissue growth and/or the response to external stimuli. The purpose of this study was to determine if the pattern of phosphorylation of syntenin in normal and benign breast tissue is the same as that seen in breast cancer tissue and to determine if there is a difference in the localization of syntenin protein in these lesions. Western blots were carried out using antibodies directed against each of the serine phosphorylation sites found on syntenin protein. The expression of syntenin and its location were determined by immunohistochemical staining in normal, benign and malignant breast tissue. Western blots of total syntenin protein from normal breast tissue, benign breast lesions and breast cancer tissue identified distinct bands of approximately 120 and 70 kDa, as well as a weak band of approximately 130 kDa. Immunohistochemical staining showed syntenin to be expressed in the same fashion in normal and benign breast tissue, while normal tissue showed expression of syntenin in the epithelial and stromal cells, while staining in benign lesions was restricted to the epithelial cells. This study shows that syntenin undergoes extensive phosphorylation in normal and benign breast tissue and that the pattern of phosphorylation of syntenin in these lesions is similar to that observed in breast cancer tissue. Furthermore, we show that syntenin is localized in the cytoplasm of the normal epithelial cells. 0 . S o l v e - w \* k - 1 5 = 0 , - 2 \* k - 1 3 = - 4 \* y + y f o r y . 1 L e t z ( v ) = 2d92ce491b
