Deleting unnecessary layers If you're not sure what you're doing, don't add layers just because you can. It will be difficult to remove those layers if you need to. When creating an image, Photoshop sometimes creates new layers. If an element such as a logo or title appears in an image and isn't immediately a layer, you can add it as a selection (which is a shape in the middle of the image) and then create a layer. This way you can easily edit and move it around and remove it, but you don't have to create a new layer for each image element.

1. Technical Field The present disclosure relates to a catheter apparatus and, more particularly, to a catheter apparatus configured to provide localized heating in a defined region of a subject's tissue. 2. Background of Related Art Localized heating of soft tissues in and around internal cavities has become a desirable treatment in a variety of different medical conditions. For example, ablation of various tissues is typically used to treat cardiac arrhythmias by destroying the tissue that will disrupt the abnormal patterns of electrical activity believed to be responsible for the arrhythmia. Localized heating of soft tissue may also be used to treat certain malignant tumors. Localized heating destroys the tissue through thermal necrosis, which may be distinguished from thermal coagulation, which may char or denature proteins, but does not actually destroy the tissue. A variety of treatment protocols are currently employed for achieving the localized heating in a body region, such as the heart. The standard ablation protocol involves positioning a radio frequency ("RF") probe at the target site to be treated, including the front and back surfaces of the heart wall, and delivering power to the probe. RF ablation probes are typically inserted into the heart through a catheter, and are guided to the target site by a cardiovascular imaging system, such as a

fluoroscopy system. The tissue is typically treated by applying energy to the tissue located at the tip of the probe, which is typically heated to about 50 to 100° C. by an internal heating element. This creates a lesion, which may be a region of coagulation and/or necrosis of tissue, on the order of about 5 to 20 mm in length. This ablation procedure is repeated until a desired lesion is formed or until a predetermined total energy level is exceeded. The above described traditional method of ablating tissue is a passive heating method. In some cases, other active systems are available. For example, some HF or microwave frequency systems may be used to treat some areas. Conventional techniques are however, limited in that they usually are unable to use imaging to assess the effectiveness of the treatment. If active heating is used, some techniques are available to evaluate and determine the effectiveness of the treatment. For example, it is possible to use a standard impedance system to map and estimate lesion size. This is typically achieved by implanting one or more electrodes into the region to be treated and applying the appropriate electrical current to the electrodes to give a current density and characteristic impedance.
