The impact of weak mixing on molecular water/electrolyte association. This paper provides a molecular/microscopic explanation of the observed weak-mixing behavior of water/salt solutions (in particular, ionic strength effects on the stability of the water/salt hydrogen-bonded networks). We show that when the guest molecule rotates much faster than the solvent molecules, (i) the first-shell water molecules are energetically favorable to the electrolyte ions because of the relaxed coherence of the solvent's fast rotation and (ii) the water molecules can migrate to the electrolyte ions' second coordination shell. This, in turn, reduces the overall attraction between the water molecules and the electrolyte ions. A simple model is used to illustrate these ideas. This application is a continuation of U.S. patent application Ser. No. 13/917,101, filed on Aug. 23, 2013, which is a continuation of U.S. patent application Ser.
